May 28, 2002

#### Abstract

There exist three filtering algorithms for batch processing with sequence dependent setup times: edge-finding, not-first/not-last and not-before/not-after. In this paper we propose another filtering algorithm called sequence composition. This algorithm can be used together with the previous three for even better pruning of search space. However, experimental results show that sequence composition is slow and yield only a few domain reductions.

## 1 Introduction

In ours previous work (Vilím and Barták 2002b) we proposed some filtering algorithms for batch processing with sequence dependent setup times. In this paper we describe one more algorithm - sequence composition. Each of these algorithms find different sort of inconsistencies therefore they can be used together.

This technical report closely bear on the paper (Vilím and Barták 2002b), we will use the notation, definitions and functions from this paper without explaining them again.

Consider following problem consisting of four tasks $T=\{1,2,3,4\}$, three families $F=\{1,2,3\}$ and machine with capacity $C=2$ :

$$
\begin{aligned}
& \forall f, g \in F: s_{f g}= \begin{cases}0 \text { when } f=g \\
1 \text { when } f \neq g\end{cases} \\
& \forall f \in F: p_{f}=1
\end{aligned} \begin{array}{lll}
f_{1}=1, & r_{1}=0, & d_{1}=5, \\
f_{2}=2, & c_{2}=0, & d_{2}=5, \\
f_{2}=2 \\
f_{3}=3, & r_{3}=0, & d_{3}=3, \\
f_{4}=3, & c_{3}=1 \\
f_{4}=2, & d_{4}=5, & c_{4}=1
\end{array}
$$

This problem has only two solutions. One of them is on the following picture, the second one is the same but the tasks 1 and 2 are swaped.

[^0]

Edge-finding, not-first/not-last and not-before/not-after do not deduce any change of time bounds. However we see that $r_{3}$ and $d_{4}$ can be changed to: $r_{3}=2, d_{4}=3$. This the motivation for our algorithm.

The idea of sequence composition is to find out that two or more activities of the same type have to be processed without interruption by different family. From this knowledge we can find the change of the time bounds.

The paper is organized as follows: first we establish new precomputed function $q$, in the next section we show how to detect some sets of uninterruptible activities and propose the filtering rules. Finally we build up filtering algorithm and conclude with some experimental results.

## 2 Setup Time with Interruption

We need to recognize when the interruption between the activites with the same family is not possible. For that we need to now how long would be the setups when the interruption occurs. Therefore we define function $q$ similar to function $s$ (see Vilím and Barták 2002b). Value of $q(f, g, \phi)$ is the minimal setup time needed for processing the activities with families $\phi$ under the condition that the processing starts with an activity with family $f \in \phi$ and the processing of the the family $g \in \phi$ is interrupted at least once by an activity with the type from $\phi \backslash\{g\}$. The values of the function $q(f, g, \phi)$ can be computed in time $O\left(k^{3} 2^{k}\right)$ using the following inductive formulas:

$$
\begin{gathered}
\forall f \in F: \quad q(f, f,\{f\})=\infty \\
\forall \phi \subset F, \phi \neq \emptyset, \forall f \in(F \backslash \phi), \forall g \in \phi: \\
q(f, f, \phi \cup\{f\})=\min \left\{s_{f h}+s(h, \phi \cup\{f\}), h \in \phi\right\} \\
q(f, g, \phi \cup\{f\})=\min \left\{s_{f h}+q(h, g, \phi), h \in \phi\right\}
\end{gathered}
$$

When we do not care which family actually starts the processing we omit the first argument. Thus $q(g, \phi)$ is a minimal setup time needed for processing the activities with families $\phi$ under the condition that the processing of family $g$ is interrupted at least once by an activity with type from $\phi \backslash\{g\}$. The function $q(g, \phi)$ is defined by the following formula:

$$
\forall \phi \subset F, \forall g \in \phi: \quad q(g, \phi)=\min \{q(f, g, \phi), f \in \phi\}
$$

## 3 Sequence Composition Rules

As mentioned above we try find out when the processing of one family family cannot be interrupted by an activity with different family. Consider a family $g$ and a set of tasks $\Omega$ which contains at least two activities with the family $g$. If we interrupt processing of the family $g$ by some activity $j \in \Omega, f_{j} \neq g$, then the processing of activities $\Omega$ takes at least the time:

$$
v(\Omega, g)= \begin{cases}q\left(F_{\Omega}, g\right)+u(\Omega) & \text { when } u(\Omega, g)>p_{g} \\ q\left(F_{\Omega}, g\right)+u(\Omega)+p_{g} & \text { when } u(\Omega, g)=p_{g}\end{cases}
$$

It is possible that there is not enough time for such interruption:

$$
\begin{equation*}
d_{\Omega}-r_{\Omega}<v(\Omega, g) \tag{1}
\end{equation*}
$$

In this case all the activities from $\Omega$ with the family $g$ have to be processed without interruption by another activities from $\Omega$. The interruption still can occur but only by an activity from $T \backslash \Omega$ (and with the family that is not in $F_{\Omega}$ ). The following figure shows an example of such interruption:

Anyway, processing of all the activities from $\Omega$ with the family $g$ (including possible interruptions by activities from $T \backslash \Omega$ ) cannot take longer than $u(\Omega, g)+m(\Omega)$, where $m(\Omega)$ is the slack (free time) in $\Omega$ :

$$
m(\Omega)=d_{\Omega}-r_{\Omega}
$$

In order to process the activity $i$ with the family $g$ together with the other activities of the family $g$, we cannot start processing of the family $g$ before $r_{i}+p_{g}-u(\Omega, g)-m(\Omega)$ :

Similarly, processing of the family $g$ cannot complete after $d_{i}-p_{g}+u(\Omega, g)+m(\Omega)$. When we combine the above deductions for all the activities of the family $g$ from the set $\Omega$, we get that processing of the family $g$ can't start before the time $t_{1}(\Omega)$ and complete after the time $t_{2}(\Omega)$ :

$$
\begin{aligned}
& t_{1}(\Omega)=\max \left\{r_{i}, i \in \Omega \& f_{i}=g\right\}+p_{g}-u(\Omega, g)-m(\Omega) \\
& t_{2}(\Omega)=\min \left\{d_{i}, i \in \Omega \& f_{i}=g\right\}-p_{g}+u(\Omega, g)+m(\Omega)
\end{aligned}
$$

It is possible that $t_{1}(\Omega)<r_{\Omega}$ or $t_{2}(\Omega)>d_{\Omega}$. Hence we introduce the new values $t_{1}^{\prime}(\Omega)$ and $t_{2}^{\prime}(\Omega)$ :

$$
\begin{aligned}
& t_{1}^{\prime}(\Omega)=\max \left\{t_{1}(\Omega), r_{\Omega}\right\} \\
& t_{2}^{\prime}(\Omega)=\min \left\{t_{2}(\Omega), d_{\Omega}\right\}
\end{aligned}
$$

All the activities with family $g$ in the set $\Omega$ have to be processed in the interval $\left\langle t_{1}^{\prime}(\Omega), t_{2}^{\prime}(\Omega)\right\rangle$. When we process only such activities in this interval then there is a slack:

$$
m^{\prime}(\Omega)=t_{2}^{\prime}(\Omega)-t_{1}^{\prime}(\Omega)-u(\Omega, g)
$$

The first batch in the sequence have to start in the interval $\left\langle t_{1}^{\prime}(\Omega), t_{1}^{\prime}(\Omega)+m^{\prime}(\Omega)\right\rangle$, the second batch in the interval $\left\langle t_{1}^{\prime}(\Omega)+p_{g}, t_{1}^{\prime}(\Omega)+p_{g}+m^{\prime}(\Omega)\right\rangle$ etc.:

Although we do not know yet, which activity will be in the first batch etc., we can still deduce the new time windows for the activities of the family $g$. The new values for $r_{j}$ and $d_{j}$ must be in the following union of intervals:

$$
\begin{align*}
& r_{j} \in \bigcup_{l \in \mathbb{N}_{0}}\left\langle t_{1}^{\prime}(\Omega)+l p_{g}, t_{1}^{\prime}(\Omega)+l p_{g}+m^{\prime}(\Omega)\right\rangle  \tag{2}\\
& d_{j} \in \bigcup_{l \in \mathbb{N}_{0}}\left\langle t_{2}^{\prime}(\Omega)-l p_{g}-m^{\prime}(\Omega), t_{2}^{\prime}(\Omega)-l p_{g}\right\rangle \tag{3}
\end{align*}
$$

Notice that the above union of intervals is in fact a single interval modulo $p_{g}$. Let us define $\Lambda(a, b, c)$ :

$$
\Lambda(a, b, c)=\{a \bmod c,(a+1) \bmod c, \ldots, b \bmod c\}
$$

The set $\Lambda(a, b, c)$ is an interval in $(\mathbb{N} \bmod c)$ so we can represent it by two values only the lower bound and the upper bound. The intersection of two such intervals $\Lambda(a, b, c)$ and $\Lambda(d, e, c)$ is again an interval in the form $\Lambda(x, y, c)$. Such intersection can be found in the time $O(1)$.

Now we can rewrite the rules (2) and (3) using $\Lambda$ :

$$
\begin{align*}
r_{i} & \geq t_{1}(\Omega)  \tag{4}\\
r_{i} \bmod p_{g} & \in \Lambda\left(t_{1}^{\prime}(\Omega), t_{1}^{\prime}(\Omega)+m^{\prime}(\Omega), p_{g}\right)  \tag{5}\\
d_{i} & \leq t_{2}(\Omega)  \tag{6}\\
d_{i} \bmod p_{g} & \in \Lambda\left(t_{2}^{\prime}(\Omega)-m^{\prime}(\Omega), t_{2}^{\prime}(\Omega), p_{g}\right) \tag{7}
\end{align*}
$$

## 4 The Algorithm Sequence Composition

It is not necessary to apply the rules for all the sets $\Omega \subseteq T$ :
Theorem 1 To find all the changes resulting from the rules (1), (2), and (3) it is sufficient to choose all the sets $\Omega$ in the form of a tasks interval.

Proof: Let us consider an arbitrary set $\Omega$. Let $\Psi$ denotes the set:

$$
\Psi=\left\{i, i \in T \& r_{i} \geq r_{\Omega} \& d_{i} \leq d_{\Omega}\right\}
$$

The set $\Psi$ is a tasks interval and we are going to show that the above rules deduce the same or even better change of $r_{i}$ for the set $\Psi$ in comparison to set $\Omega$. It is obvious that:

$$
\begin{aligned}
\Psi & \supseteq \Omega \\
r_{\Psi} & =r_{\Omega} \\
d_{\Psi} & =d_{\Omega}
\end{aligned}
$$

Hence $v(\Omega, g) \leq v(\Psi, g)$ for an arbitrary family $g$. Because (1) holds for $\Omega$ it have to hold for $\Psi$ as well. From the above three formulae we deduce:

$$
\begin{aligned}
m(\Psi) & \leq m(\Omega) \\
u(\Psi, g) & \geq u(\Omega, g) \\
\max \left\{r_{i}, i \in \Psi \& f_{i}=g\right\} & \geq \max \left\{r_{i}, i \in \Omega \& f_{i}=g\right\} \\
\min \left\{d_{i}, i \in \Psi \& f_{i}=g\right\} & \leq \min \left\{d_{i}, i \in \Omega \& f_{i}=g\right\} \\
t_{1}(\Psi) & \geq t_{1}(\Omega) \\
t_{2}(\Psi) & \leq t_{2}(\Omega) \\
t_{1}^{\prime}(\Psi) & \geq t_{1}^{\prime}(\Omega) \\
t_{2}^{\prime}(\Psi) & \leq t_{2}^{\prime}(\Omega) \\
m^{\prime}(\Psi) & \leq m^{\prime}(\Omega)
\end{aligned}
$$

Because the difference between $u(\Psi, g)$ and $u(\Omega, g)$ cannot be bigger than the difference between $m(\Omega)$ and $m(\Psi)$, the following inequality holds: $u(\Omega, g)+m(\Omega) \geq u(\Psi, g)+$ $m(\Psi)$.

So the changes of $r_{i}$ and $d_{i}$ deduced by the rules (4) and (5) applied on the set $\Psi$ are at least as good as the changes deduced by the same rules applied on the set $\Omega$.

When we change the value $r_{i}$ using the rule (5) for the set $\Omega_{1}$, it may happen than after the second change using the same rule but another set $\Omega_{2}$ the new value for $r_{i}$ does not match with the rule (5) and the set $\Omega_{1}$. Therefore we do not change the values $r_{i}$ immediately but we write down the intervals $\Lambda_{r}$ and $\Lambda_{d}$ for the values $\left(r_{i} \bmod p_{i}\right)$ and $\left(d_{i} \bmod p_{i}\right)$. Then we compute the intersection of all such intervals and finally we make the changes of $r_{i}$ and $d_{i}$.

Let us choose an activity $j$ and a family $g$. We create the sequence of all the tasks intervals $\Omega_{0} \subseteq \Omega_{1} \subseteq \cdots \subseteq \Omega_{x}$ such that $d_{j}=d_{\Omega_{0}}=d_{\Omega_{1}}=\cdots=d_{\Omega_{x}}$. Let us introduce a new notation:

$$
\begin{aligned}
n(\Omega, f)= & \left|\left\{k, k \in \Omega \& f_{k}=f\right\}\right| \\
M(i)= & \{l, l \in\{i, i+1, \ldots, x\} \& \\
& \left.d_{\Omega_{l}}-r_{\Omega_{l}}<v\left(\Omega_{l}, g\right) \& n\left(\Omega_{l}, g\right) \geq 2\right\} \\
t_{1}(i)= & \max \left\{t_{1}\left(\Omega_{l}\right), l \in M(i)\right\} \\
t_{2}(i)= & \min \left\{t_{2}\left(\Omega_{l}\right), l \in M(i)\right\} \\
\Lambda_{r}(i)= & \bigcap_{l \in M(i)} \Lambda\left(t_{1}^{\prime}\left(\Omega_{l}\right), t_{1}^{\prime}\left(\Omega_{l}\right)+m^{\prime}\left(\Omega_{l}\right), p_{g}\right) \\
\Lambda_{d}(i)= & \bigcap_{l \in M(i)} \Lambda\left(t_{2}^{\prime}\left(\Omega_{l}\right)-m^{\prime}\left(\Omega_{l}\right), t_{2}^{\prime}\left(\Omega_{l}\right), p_{g}\right)
\end{aligned}
$$

For a given activity $j$ and a family $g$ we can compute all the values $t_{1}(i), t_{2}(i), \Lambda_{r}(i), \Lambda_{d}(i)$ in time $O(n)$.

Now consider an activity $k$ of a family $g$ such that $k \in \Omega_{i}$ and $k \notin \Omega_{i-1}$. The rules (1), (2), and (3) for the activity $k$ and the sets $\Omega$ such as $d_{\Omega}=d_{j}$ deduce exactly:

$$
\begin{aligned}
r_{i} & \geq t_{1}(i) \\
r_{i} \bmod p_{g} & \in \Lambda_{r}(i) \\
d_{i} & \leq t_{2}(i) \\
d_{i} \bmod p_{g} & \in \Lambda_{r}(i)
\end{aligned}
$$

The above formulae are the basis of the filtering algorithm. We expect that all the activities are sorted in the decreasing order of $r_{i}$. The time time complexity of this algorithm is $O\left(k n^{2}\right)$.

```
for i\inT do begin
    // lr is the set of possible values r}\mp@subsup{r}{i}{}\operatorname{mod}\mp@subsup{p}{\mp@subsup{f}{i}{}}{}\mathrm{ :

                r}k\geq\mp@subsup{t}{1}{}(i)
                d
                lr}[\textrm{k}]:=\operatorname{lr}[\textrm{k}]\cap\mp@subsup{\Lambda}{r}{}(i)
                ld[k]:= ld [k]\cap \Lambda ( (i);
                k := next activity with the same or greater r r ;
            end else
                // We already went over all activities }k\mathrm{ such that }\mp@subsup{f}{k}{}=g,k\in\mp@subsup{\Omega}{i}{}\mathrm{ and }k\not\in\mp@subsup{\Omega}{i-1}{}
                // So continue with }\mp@subsup{\Omega}{i-1}{}\mathrm{ :
                i := i-1;
        end;
    end;
end;
for i\inT do begin
    if }\operatorname{lr}[i]=\emptyset\mathrm{ or ld [i]= Ø then fail ;
    r}i:= the smallest integer greater or equal ris such that rim mod p p\mp@subsup{f}{i}{}\in\operatorname{lr}[\textrm{i}]
    di}:=\mathrm{ the greatest integer lower or equal }\mp@subsup{d}{i}{}\mathrm{ such that }\mp@subsup{d}{i}{}\operatorname{mod}\mp@subsup{p}{\mp@subsup{f}{i}{}}{}\in\operatorname{ld}[\textrm{i}]
end;
```

## 5 Experimental Results

The individual filtering techniques have been combined into a single filtering algorithm accordingly to (Vilím and Barták 2002b). New algorithm sequence composition is in the outermost loop because most of the time it do not deduce new reductions:

```
repeat
    repeat
        repeat
            repeat
                    consistency check
                    edge-finding
            until no more changes found
            not-before/not-after
        until no more changes found
        not-first/not-last
    until no more changes found
    sequence composition
until no more changes found
```

As the benchmark set we used (Vilím and Barták 2002a). For each problem we measured the computer time ${ }^{1}$ and number of backtracks with and without the sequence composition. We measured number of reductions made by sequence composition. These reductions are of two types:

Reductions 1: from the rules (4) and (6), i.e. $r_{i} \geq t_{1}(\Omega)$ and $d_{i} \leq t_{2}(\Omega)$.
Reductions 2: from the rules (5) and (7), i.e:

$$
\begin{aligned}
& r_{i} \bmod p_{g} \in \Lambda\left(t_{1}^{\prime}(\Omega), t_{1}^{\prime}(\Omega)+m^{\prime}(\Omega), p_{g}\right) \\
& d_{i} \bmod p_{g} \in \Lambda\left(t_{2}^{\prime}(\Omega)-m^{\prime}(\Omega), t_{2}^{\prime}(\Omega), p_{g}\right)
\end{aligned}
$$

Table 1 shows the results.

## 6 Conclusions

Experimental results are disappointing - only for problems a and $p$ the number of backtracks is little bit lower but the CPU time bigger for all the problems. In the cases d, e, g, o, $v$ and $w$ the algorithm made some reductions but the number of backtracks stayed the same - sequence composition found some reductions, but without the sequence composition the same reductions were deduced also by another filtering algorithm somewhere deeper in the search tree.

Reduction of type 1 was not found for any of the problems. It indicates that the benchmark set is not really random. The question is how to generate better benchmark problems.
